**Abstract**

The protective effects of *Garcinia kola* against a dose of Carbon-Tetrachloride (CC₁₄) -induced liver damage in experimental rats were investigated. The CC₁₄ induction (administered intraperitoneally, 0.5ml/kg body weight in olive oil-0.5ml/kg body weight) led to significant increases in the levels of serum aspartate and alanine amino transferases, alkaline phosphatase and lipid peroxides in CC₁₄ intoxicated rats. Pretreatment with varied concentrations of *Garcinia kola* diets (1%, 5% and 10%) and vitamin E (9%,) for 21 days prior to CC₁₄ administration resulted in significant decreases in Liver marker enzymes and lipid peroxides. These findings suggest that *Garcinia kola* seed may be acting as a natural antioxidant that prevents hepatic oxidative stress induced by CC₁₄.

INTRODUCTION

The demand for therapeutic drugs from natural products is on the increase in recent times. This is traceable to the realization that plant products contain active constituents that are capable of curing majority of man’s diseases. Indeed, drugs of natural origin are the only widely used hepatoprotectives. Garcinia kola belongs to the Family Clusiaceae guttiferae and contains a complex mixture of biflavonoids, prenylated benzophenones and xanthones. The plant has shown anti-inflammatory, antimicrobial, pharmacological and antiviral properties. It has been confirmed that seeds of Garcinia kola contain energy-yielding nutrients (proteins, lipids, carbohydrates) and minute quantities of Kolaviron (consisting of biflavonoids GB-1, GB-2 and Kolaflavone). The seeds of Garcinia kola have been employed in many herbal preparations in Nigeria for the treatment of ailments ranging from laryngitis, bronchitis to liver disorders.

Trichloromethyl radicals are generated from CC1₄, in vivo, which stimulate a sequence of biochemical reactions that lead to the initiation of lipid membrane peroxidation. The ethanol inducible isoform of the P₄₅₀ cytochrome is believed to play an active role in this process. Indeed, the process of CC1₄-induction of lipid peroxidation provides useful information that could be explored in examining antioxidant properties of natural products. The aim of this study was to assess the ability of Garcinia kola seeds to exhibit antioxidant actions against CC1₄-induced liver damage in rats.

MATERIALS AND METHODS

The seeds of Garcinia kola (purchased from Choba market in Rivers State, Nigeria) were peeled, sliced and dried in the air for 5 days. The dried, sliced feeds were ground into flour with an electric blender (Model MX – 795N-National). Male albino rats of the Wistar strain (140g-160g) were obtained from the University of Port Harcourt animal house. They were housed in Griffin and George modular cage system and left to acclimatize to laboratory conditions for 7 days prior to commencement of work. The animals were fed with a commercial pelleted diet (purchased from Top Feeds, Nigeria Ltd. Port Harcourt, Nigeria) and water ad libitum.

Experimental procedure

The rats were divided into six groups with each group comprising five animals. Rats in groups 1 and 2 received the pelleted diet and water, while those in groups 3, 4 and 5 were fed with diet formulated with the flour of Garcinia kola and rat pellets as follows: group 3-1% flour of G. cola; group 4-5% flour of G. cola; group 5-10% flour of G. cola

Also, animals in group 6 received diet compounded with vitamin E and rat pellets (9% vitamin E). All the rats in the various groups received their respective diets and water ad libitum for 21 days. On the 22nd day of the experiment, CCl₄ (0.5ml/kg body weight in 0.5 olive oil) was administered intraperitoneally to rats in groups 2, 3, 4, 5 and 6. The animals were allowed to fast for 24 hours after which they were anaesthetized in a chloroform saturated chamber. Blood samples were obtained by cardiac puncture from each rat by means of a 5ml hypodermic syringe and needle. The blood samples were introduced into clean, dry bottles without anticoagulants for serum separation. The bottles and its contents were centrifuged at 5000g for 10 minutes (model: MSE – Minor 35 centrifuge). Serum was collected into a clean, dry sample container. The serum levels of L-aspartate aminotransferase (AST), L-alanine transferase (ALT) and alkaline phosphatase (ALP) were measured spectrophotometrically as described by Verly. The liver was excised, washed in ice-cold saline, and homogenized at 0.1 M Tris-HCl buffer (pH 7.4; 4°C) in a homogenizer at 600 rpm for 4 minutes using mortar and pestle. The liver homogenate was employed in assaying the activities of the lipid peroxides as described by Hunter et. al. and modified by Gutteridge and Wilkins. The mean values of the various groups were compared using analysis of variance (ANOVA) and the level of significance was set at p ≤ 0.05.
RESULTS
The effects of pretreatment with seeds of *Garcinia kola* and vitamin E, 21 days prior to CC1₄ administration on liver enzymes and lipid peroxides in rats is shown in figures 1 and 2.

**Fig. 1**: Effects of varied levels of *Garcinia kola* and Vitamin E on liver enzymes of rats administered CC1₄ (mean ± STD; n=5 in each group). *Values of enzymes with different letters (a, b, c, d, e) in the respective groups are significantly different at P≤0.05

**Fig. 2**: Activities of lipid peroxides in rats pretreated with *Garcinia kola* seed and Vitamin E prior to CC1₄ administration.
Group 2 rats that received a single dose of CC14 showed marked elevation in the levels of liver enzymes when compared with those of the group 1 (control) rats. The pretreated groups 3, 4, 5 and 6 rats showed remarkable decline in the levels of AST, ALT and ALP when compared with group 2 rats that received CC14 alone.

In the liver tissue, increased levels of lipid peroxides were recorded in the group 2 rats (figure 2). The activities of the peroxides decreased with increase in the amount of the seeds of Garcinia kola in the feed formula. This is evidenced in the values obtained in rats in groups 3, 4, and 5. Similarly, rats in group 6 recorded malondialdehyde values close to those of group 5 and 1 (control) rats.

DISCUSSION

As elicited by the elevation in the levels of liver marker enzymes (AST, ALT, ALP), CC14 administration resulted in a significant hepatic damage. Obviously, the elevated levels of these biochemical parameters are a direct reflection of alterations in the hepatic structural integrity. The results of the enzymes obtained in this study corroborates those of Obi, et. al.7 and Reinke, et. al.5 who reported elevated levels in the serum content of hepatic enzymes in rats administered with CC14. In particular, the elevation of ALT is indicative of liver damage12,13. These enzymes are located in the cell cytoplasm and are emptied into the circulation once the cellular membrane is damaged14,15. There is a growing consensus among workers that CC14-induced liver damage occur by the production of a trichloromethyl radical from CC14 when it is reductively dechlorinated. The trichloromethyl radical production abstracts a hydrogen atom from fatty acid to form a lipid radical that reacts with molecular oxygen. The product of such reaction is the initiation of lipid peroxidation16,17.

Since the above mechanism is suggestive of the process of oxidative stress, it is true, therefore, that any natural product with antioxidant property will prevent or reverse lipid peroxidation; including cell membrane damage. The report of Iwu4 that implicated seeds of Garcinia kola in folk medicine and herbal preparations for treatment of liver disorders, informed the screening of its natural antioxidant properties. We also reasoned that a comparison of the results obtained with those of vitamin E (rated as one of the most powerful antioxidants) would positively influence our position on its antioxidant status.

The findings in this study shows that pretreatment of rats 21 days prior to CC14 administration caused a marked decrease in the levels of hepatospecific serum enzymes. This suggests that seeds of Garcinia kola may be protective against CC14-induced liver damage in rats. This was ascertained by a comparative analysis of the results obtained in rats pretreated with Garcinia kola and vitamin E.

Malondialdehyde (MDA) is a product of lipid peroxidation9. An increase in the liver MDA levels is an indication of elevated level of lipid peroxidation17. Extensive lipid peroxidation leads to disorganization of membrane by peroxidation of unsaturated fatty acids which also alters the ratio of poly-unsaturated to other fatty acids. This would lead to a decrease in the membrane fluidity and the death of cell9.

Conclusion

The marked decrease in the levels of lipid peroxides recorded in rats pretreated with Garcinia kola seeds suggests that the seed may possess the natural antioxidants necessary for protection against free radical damage induced by CC14 in rat liver.
