A 48-year-old male patient with diabetes mellitus and retinitis pigmentosa was admitted with complaints of weakness of both lower limbs and urinary incontinence of 1-year duration. Fundoscopy was suggestive of retinitis pigmentosa. On admission, the power in the legs was about Grade 2. Plain X-ray showed a sickle-shaped defect of the sacrum - scimitar sacrum (Figure 1). MRI showed an anterior presacral meningocele with scalloping and dehiscence of the anterior wall of the lower half of the left side of the sacrum (Figure 2). Repair of anterior sacral meningocele was done by a posterior approach. The patient showed improvement following surgery and at one-year follow-up, he has regained his bladder control and is ambulant with 4/5 power in the lower limbs.
