South American histicognath rodents Thrichomys aperoioides laurentius and Thrichomys pachyurus are natural hosts of Trypanosoma cruzi, agent of Chagas disease. We established breeding colonies of these species to serve as experimental models in various parasitological studies. Both species of Thrichomys have all the requirements necessary to become excellent laboratory models: they can be easily maintained in the standard laboratory conditions and breed throughout the year and they do not have any special dietary demands and can be fed by standard food pellets designed for laboratory mice. Both species produce precocious offspring that have their eyes and ears open, teeth erupted, fur well developed, and can eat solid food in the first week of life. T. a. laurentius has larger litter sizes and lower body masses at birth and weaning than T. pachyurus. Moreover, females of T. a. laurentius reach puberty earlier and with lower body mass than T. pachyurus.

Key words: breeding - reproduction - development - Thrichomys

Bio-medical research is critically dependent on availability of adequate animal models. Progress in understanding of fundamental principles of physiology, endocrinology, development, reproductive and behavioral biology of mammals would be impossible without the use of various strains of mice, rats, hamsters, and other non common laboratory species. Studies in these model animals have made possible breakthroughs in treatment of many hereditary and infectious human diseases (Kumar et al. 1994). However, several of these models are not adequate animal models. Both species of Thrichomys have all the requirements necessary to become excellent laboratory models: they can be easily maintained in the standard laboratory conditions and breed throughout the year and they do not have any special dietary demands and can be fed by standard food pellets designed for laboratory mice. Both species produce precocious offspring that have their eyes and ears open, teeth erupted, fur well developed, and can eat solid food in the first week of life. T. a. laurentius has larger litter sizes and lower body masses at birth and weaning than T. pachyurus. Moreover, females of T. a. laurentius reach puberty earlier and with lower body mass than T. pachyurus.

MATERIALS AND METHODS

The colony of T. a. laurentius was derived from 9 males and 38 females captured in the National Park Serra da Capivara and surroundings in southeastern Piauí (Caatinga biome). T. pachyurus colony was derived from 9 males and 34 females captured in municipality of
Corumbá, in southwestern Mato Grosso do Sul (Pantanal biome).

The wild caught animals were screened for trypanosomes, hantaviruses, and rickettsias and were treated with Ivermectin and anti-flea talcum to remove helminths and ectoparasites. They were kept in a quarantine building for 40 days and then transferred to the animal house of the Department of Tropical Medicine, of the Oswaldo Cruz Institute, Rio de Janeiro, where they were kept under conventional conditions (temperature 22-26°C, natural daylight). The animals were marked by individual subcutaneous microchip (Trovan®, Aeg & Telefunken Electronics, Nürnberg, Germany).

Single animals were housed in 41- by 34- by 17 cm polypropylene cages. The breeding pairs and lactating females were housed in 66- by 57- by 23 cm cages, with a sawdust substrate. The cages were cleaned once a week. Water and food was provided ad libitum. The diet consists of NUVILAB CR1 mouse pellets (Nuvital Nutrients S.A., Colombo/PR, Brazil). No fresh food supplements were used.

Usually breeding pairs were kept together for 15 days. To estimate gestation time we kept breeding pairs together for only one day. The mated females were examined daily for signs of birth. Litter size, sex, ratio, and body mass at birth were determined within 24 h after parturition. The offspring were weaned on day 21 according to Roberts et al. (1988). Female sexual maturation was operationally defined as the weight and the age at vaginal opening, according to other studies (D’Andrea et al. 1996).

All procedures followed protocols licensed by the Committees of Biosafety and Bioethics of the Oswaldo Cruz Institute.

We used the student’s t test to compare litter size and sexual maturation times between species, and birth and weaning masses, between species and sexes. We used Chi square to compare sex ratio at birth, postnatal mortality and breeding success.

**RESULTS**

**Handling** - The animals of both species do not show obvious signs of distress in laboratory conditions, although we found that specimens of *T. pachyurus* were more excitable than those of *T. a. laurentius*. A special precaution should be taken with punarés during laboratorial manipulations. The animals of both species, as well as other echimyid rodents, have very fragile skin and the tail may be ruptured when tensioned. Therefore we do not recommend manipulating them with forceps or handling them by the tail. We usually fix the neck of an animal with index and middle fingers and then hold the body with thumb and fourth finger. The animals rarely try to bite, but it is necessary to use thick rubber gloves during manipulation.

**Blood sampling** - We tried several methods of blood collection in punarés. The best results were achieved by intracardiac blood sampling. The animals were anesthetized with intramuscular injection of ketamine at the dose 100 mg/kg. They displayed a great individual variability in their reaction to the same dose of ketamine. It seems that *T. a. laurentius* was more sensitive to the anesthetic effect of this drug than *T. pachyurus* because they tended to be anesthetized more quickly than *T. pachyurus* (personal observation). The anesthetized animals were fixed, the skin was sterilized and the blood was collected with 5 ml syringe. Up to 2 ml blood can be collected without any serious damage to the animal.

Blood collection from the retrobulbar plexus was less time consuming, although less effective in terms of the quantity of blood collected (no more than 1 ml). The procedure was carried out under local anesthesia with colirium (0.5% solution of proximetaacaine chloride).

We do not recommend the collection of blood from the femoral vein. In punaré it is very sensitive and hard to stop the bleeding. As we mentioned above punaré tails are very fragile and for this reason we do not recommend blood collection from the caudal vein. However, small blood samples for serological and molecular genetic analyses can be taken from the tail tip.

**Breeding** - Breeding punarés in captivity was relatively simple. The breeding pairs rarely displayed agonistic behavior. We detected physical confrontation in only 2% of mating pairs of *T. a. laurentius* and 6% of *T. pachyurus*.

Average breeding success was the same in *T. pachyurus* and *T. a. laurentius* ($\chi^2 = 0.03; df = 1; p = 0.866$) (Table). In pairs with less than two years, success reached 40-50%, and gradually decreased after the second year of reproduction. Both colonies produced off-

*a*: difference between the species is significant ($p < 0.05$); *b*: sex difference is significant ($p < 0.05$)
spring throughout the year and did not show any reproductive seasonality.

**Litter size and body mass** - Mean litter size was significantly higher in *T. a. laurentius* colony than in *T. pachyurus* (*t* = 2.19; *df* = 32; *p* = 0.035) (Table). The litter size variation in *T. a. laurentius* (range: 1-6) was similar to that described by Roberts et al. (1988) for captive breed colony of punaré derived from Northeastern Brazil. *T. pachyurus* displayed a narrower range of variation (from 1 to 4). Sex ratio at birth did not differ from the expected 1:1 ratio in both species (*T. pachyurus*: $\chi^2 = 14.3$; *df* = 20; *p* > 0.05, *T. a. laurentius*: $\chi^2 = 16.7$; *df* = 10; *p* > 0.05). Postnatal mortality was the same in *T. pachyurus* and *T. a. laurentius* ($\chi^2 = 3.14$; *df* = 1; *p* = 0.08) (Table).

Sex difference in body mass at birth and at weaning was not significant in *T. a. laurentius* (*t* = 0.24; *df* = 74; *p* = 0.810, *t* = 1.13; *df* = 77; *p* = 0.262, respectively). In *T. pachyurus* this difference was significant and the males tended to be larger than females (*t* = 2.31; *df* = 19; *p* = 0.032, *t* = 2.28; *df* = 10; *p* = 0.045, respectively). Average body mass at birth and at weaning was higher in *T. pachyurus* than in *T. a. laurentius* (*t* = 10.54; *df* = 95; *p* = 0.0012 × 10^{-14} and *t* = 10.18; *df* = 89; *p* = 0.0013 × 10^{-13}, respectively) (Table).

**Development** - There was a significant difference between the species in the age and body mass at sexual maturation (*t* = 3.28; *df* = 66; *p* = 0.00168, *t* = 6.328; *df* = 65; *p* < 0.0026 × 10^{-5}, respectively). Females of *T. a. laurentius* reached sexual maturation at six weeks and *T. pachyurus* two weeks later (Table).

The gestation period was estimated in one female of *T. pachyurus* (105 days) and five females of *T. a. laurentius* (95.4 ± 1.4 days). This is in good accordance with the data of Roberts et al. (1988). Newborns of both species were precocious and had their eyes and ears open, teeth erupted, fur well developed and were able to eat solid food in the first week of life.

Up to the moment of writing this paper the oldest captive born specimens of *T. pachyurus* are 4 years old and those of *T. a. laurentius* are 5 years old.

**DISCUSSION**

Both species of *Thrichomys* meet all requirements to become suitable laboratory animal models for the study of parasitic diseases. They can be easily maintained in standard laboratory conditions and breed throughout the year. Illness such as viral infections and diarrhoea were never observed. They do not have any special dietary demands and can be fed by standard food pellets designed for laboratory mice.

The breeding colonies of *Thrichomys* may serve as an adequate model to study various aspects of the transmission cycle of *T. cruzi*, such as analyses of immune response dynamics to different *T. cruzi* isolates, tissue specificity of the parasite, and patterns of infection. It is worth mentioning that these animals are able to control the number of circulating parasites and maintain the infection with both *T. cruzi* I and *T. cruzi* II subpopulations, with hardly any mortality (Herrera et al. 2004b, Roque et al. 2005).

Their very long gestation time (more than 3 months) permits studies in transplacental transmission of *T. cruzi*.

*Thrichomys* is a natural host of helminths of the genus *Trichuris* Roederer, 1761. Some species of this genus infect humans and cause immune suppression (Wickelgreen 2004). Breeding colonies of *Thrichomys* have recently been used to establish the biological cycle of *Trichuris* sp. in the laboratory (Maldonado Jr A, pers. commun.).

The potential use of this model is not restricted by parasitological studies. Till now the researchers had at hand only one precocious laboratory animal – the guinea pig. *Thrichomys* may serve as an alternative model to study physiology, developmental, behavioural and reproductive biology of precocious species.

It is especially useful to have colonies of two different species which are able to produce viable hybrids because it presents opportunities for comparative and genetic analyses of various biological traits and processes.

The use of these captive breed colonies as models in parasitological and genetic studies has already produced encouraging results (Roque et al. 2002, Herrera et al. 2004b).
