Received: 2 June 2015 Revised accepted: 7 September 2015

**Abstract**

**Purpose:** To evaluate the total phenolic content and antioxidant potential of the methanol extracts of aerial parts and roots of *Thymus sipyleus* Boiss and also to determine some phenolic compounds using a newly developed and validated reversed phase high performance liquid chromatography (RP-HPLC) method.  

**Methods:** The total phenolic concentration of the extracts were determined using Folin Ciocalteu method. The antioxidative potential of the samples was evaluated using DPPH and ABTS assays. Phenolics responsible for the antioxidant activity of the plant were quantified by a newly developed and validated RP-HPLC method for the first time.  

**Results:** The total phenolic concentration of the extracts were 215.1 ± 2.24 and 152.25 ± 2.31 mg GAE/g extracts, respectively. The extract obtained from the aerial parts reduced DPPH with a half-maximal inhibition concentration (IC₅₀) of 0.703 ± 0.027 mg/mL, while the IC₅₀ obtained from ABTS assay was 0.869 ± 0.066 mg/mL. IC₅₀ values of Trolox used as standard for DPPH and ABTS radical scavenging assays were 0.0430 ± 0.0001 and 0.0420 ± 0.0001 mg/mL, respectively. The results revealed that *T. sipyleus* contains remarkable amounts of rosmarinic acid in the aerial parts (0.8887 ± 0.0016 g/100g dw) and in the roots (0.3454 ± 0.0006 g/100g dw) which is believed to be mostly responsible for the observed activity.  

**Conclusion:** *T. sipyleus* is a major potential antioxidant source for the food, pharmaceutical and cosmetic industry due to its high contents of rosmarinic acid and total phenolics.  

**Keywords:** Thymus sipyleus, Rosmarinic acid, Chlorogenic acid, Caffeic acid, Apigenin, Antioxidant

**INTRODUCTION**

Plants are valuable sources of natural compounds with different chemical and biological properties. Plant secondary metabolites and extracts are of great interest during the last few decades due to their various pharmacological activities. The wide usage of plants as food, food additives, health promoting agents and supplements has undoubtedly increased the number of studies which aim to set light to the chemical composition and biological activity of these sources [1-3].  

Oxidative stress which can be defined as the imbalance between oxidants and antioxidants, elicit several pathophysiological disorders such as cancer, aging and other diseases. It’s clear that fighting with these parameters plays an important role in the prevention of chronic diseases. It is very important to consider plants first in order to eliminate the risk of such
disorders. Numerous crude extracts and natural compounds have been reported to have antioxidant and radical scavenging properties [3-5]. Phenolic compounds like flavonoids, tannins, caffeic acid derivatives are known to be the potential antioxidants of the natural sources [2].

The Lamiaceae family is a good source of aromatic and spicy plants that have a strong antioxidant potential. Many of the aromatic plants of the Lamiaceae family grow wild in Mediterranean region. Rosmarinus, Salvia and Thymus species are the primary members of the Lamiaceae family. Among these, the members of Thymus species are very popular for their carminative, expectorant, antitussive and antioxidant characteristics and are widely used as spices, herbal teas and flavoring agents all over the World [2,6]. It has been known that there is an inverse relationship between dietary intake of antioxidant-rich foods and the incidence of a number of human diseases [7,8]. Also, natural sources like fresh and dried aromatic plants as well as their processed products have been widely used as flavouring agents for centuries. The antioxidant potential of these sources could be evaluated to extend the life span of foods and nutraceuticals that are displayed on shelf. Therefore, it is important to research into the determination of natural antioxidant sources.

The genus Thymus is one of the largest member of the Lamiaceae family and is represented by 39 species with 64 taxa in Turkey [9]. Thymus sipyleus is known as “kekik otu” and is used as a spice in Turkey [10]. Most previous studies have focused primarily on the essential oil composition of numerous Thymus taxa [11-17]. Using a different approach, this paper reports the qualitative and quantitative analysis of phenolics in different parts of Thymus sipyleus for the first time, together with antioxidant activity and total phenolic content.

**EXPERIMENTAL**

**Chemicals**

Chromatographic grade double-distilled water, HPLC grade methanol, acetonitrile and analytical grade trifluoroacetic acid were used for HPLC analysis. Folin Ciocalteu reagent and the following phenolic compounds were purchased from Sigma (Germany): rosmarinic acid (536954), chlorogenic acid (C3878), caffeic acid (C0625) and apigenin (10798). Also, DPPH (D9132) and ABTS (A1888) were purchased from Sigma (Germany). All other chemicals were of analytical grade and obtained from either Sigma (Germany) or Merck (Darmstadt, Germany).

**Materials**

Thymus sipyleus Boiss. was collected from Kibrsköyü, Ankara during its flowering period in July. The voucher specimen was deposited in the Herbarium of the Ankara University, Faculty of Pharmacy (AEF 26639).

**Extraction procedure**

For the total phenolic content and antioxidant activity tests, 5 g of air dried and milled aerial parts and roots of the plant were extracted with methanol (≥ 99.9 %, 100 mL) using a magnetic stirrer for 1 h (50 °C, 250 rpm). After filtration, methanol was evaporated completely in a rotary evaporator (Buchi-R200). The dry crude extracts were used for antioxidant activity and total phenolic content assays.

For the HPLC analysis, 200 mg of air dried and milled aerial parts and roots were extracted with methanol (≥ 99.9 %), using a magnetic stirrer, for 6 h (50 °C, 250 rpm). The extracts were then filtered, made up to 10.0 mL in a volumetric flask with methanol, passed through a 0.45 μm filter, and injected into the HPLC system.

**Determination of total phenolic content**

The total phenolic content of the extracts was determined spectrophotometrically using a modified Folin Ciocalteu method [18]. The reduction of the reagent, which resulted in the formation of a blue colour, was recorded at 765 nm. One hundred μL of the methanol extract of each plant part (2 mg/mL) was mixed with 7.9 mL of distilled water. Folin Ciocalteu reagent (500 μL) was added and the contents of the flask were vortexed. After 8 min, 1.5 mL of 20 % Na2CO₃ was added. After 2 h of incubation at room temperature, the absorbance was measured at 765 nm using a Shimadzu spectrometer. Gallic acid was used as the standard. All measurements were performed in triplicate, and the average values were used to express the mg of gallic acid equivalents (GAE)/g dry extract.

1,1-Diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity (DPPH) assay

The capacity to scavenge the stable free radical DPPH was monitored according to the modified method of Barros et al. [19]. An aliquot of each extract (0.25 mL) was mixed with 2.75 mL of the methanolic solution containing DPPH radical. The mixture was shaken vigorously and left to
stand for 10 min in the dark (until stable absorption values were obtained). The reduction of the DPPH radical was determined by measuring the absorption at 517 nm. The radical scavenging activity (D) was calculated as a percentage of DPPH discoloration as in Eq 1.

\[
D(\%) = \left(\frac{(A_B - A_S)}{A_B}\right) \times 100
\]

where As is the absorbance of the solution when the sample extract was added at a particular level, and Ab is the absorbance of the DPPH solution. The extract concentration providing 50 % inhibition (IC\textsubscript{50}) was calculated from the graph of inhibition percentage against the extract concentration. Trolox (Sigma, Germany) and caffeic acid were used as the standard.

\section*{2,2'-Azino-bis(3-ethylbenzthiazoline-6-sulphonic acid) (ABTS) assay}

ABTS radical scavenging activity was measured using a modification of the method of Re et al \cite{20}. ABTS was dissolved in methanol to a concentration of 7 mM. ABTS radical cation was produced by reaction of ABTS stock solution with 2.45 mM K\textsubscript{3}S\textsubscript{2}O\textsubscript{8} (as an oxidant for conversion of ABTS into a radical cation). The color of the resulting solution was blue-green. This radical solution was kept in the dark at room temperature for 12 - 16 h before use in precise measurements. The ABTS radical cation solution was diluted with 96 % ethanol to obtain an absorbance of 0.70 ± 0.02 at 734 nm. An aliquot of each extract (0.25 mL) was mixed with 2.75 mL of diluted ABTS radical cation solution. After the reaction at room temperature for 6 min, the reduction in absorbance at 734 nm was measured. The radical scavenging activity (B) was calculated as a percentage of ABTS inhibition as in Eq 2.

\[
B(\%) = \left(\frac{(A_B - A_S)}{A_B}\right) \times 100
\]

where As is the absorbance of the solution when the sample extract was added at a particular level, and Ab is the absorbance of the ABTS solution. The extract concentration providing 50 % inhibition (IC\textsubscript{50}) was calculated from the graph of inhibition percentage against extract concentration. Trolox (Sigma, Germany) was used as the standard.

\section*{Identification and quantification of phenolic compounds by HPLC-DAD}

The qualitative and quantitative analyses of the phenolic compounds in the extracts were performed according to the following procedure. The analysis was performed with a LC system consisting of a HP Agilent 1260 series quaternary pump, de-gasser and photo-diode array detector. The samples were injected into a HP Agilent 1260 Autosampler with a thermostated column compartment on an ACE column (5 μ, 250 mm × 4.6 mm) at 30 °C. The system was controlled and data analysis was performed using Agilent ChemStation software. All the calculations concerning the quantitative analysis were performed with external standardization by measurement of the peak areas. Gradient elution was applied with a flow rate of 0.8 mL/min and column temperature was set to 30 °C. The mobile phase was a mixture of trifluoroacetic acid 0.1 % in water (solution A), trifluoroacetic acid 0.1 % in methanol (solution B), and trifluoroacetic acid 0.1 % in acetonitrile (solution C).

The composition of the gradient was (A:B:C), 80:12:8 at 0 min, 75:15:10 at 8 min, 70:18:12 at 16 min, 65:20:15 at 24 min, 50:35:15 at 32 min, 25:60:15 at 40 min and 80:12:8 at 45 min. The duration between the runs was 2 min. All the solvents were filtered through a 0.45 μm millipore filter before use and de-gassed was in an ultrasonic bath. From each solution and sample, 10 μL was injected into the column and the chromatograms were recorded from 200 to 400 nm. Standard solutions were analyzed and three-dimensional chromatograms (wavelength; time; absorbance) were obtained to select the optimum wavelength for detection of the phenolics with maximum sensitivity. Quantification was performed by measuring all the investigated phenolics at 330 nm using a photo-diode array detector. The chromatographic run time was 45 min.

\section*{Calibration}

Five different concentrations of rosmarinic acid, chlorogenic acid, caffeic acid and apigenin were prepared in methanol ranging between 4.3-215 μg/mL, 5-250 μg/mL, 5.2-260 μg/mL and 2-100 μg/mL, respectively. 10 μL of triplicate was injected into each standard solution to see the reproducibility of the detector response at each concentration level. The peak areas obtained from the injections were plotted against the concentrations to establish the calibration graph.

\section*{Limits of detection and quantification}

The limits of detection (LOD) were established at a signal to noise ratio (S/N) of 3. The limits of quantification (LOQ) were established at a signal to noise ratio (S/N) of 10. LOD and LOQ were experimentally verified by the nine injections of reference compounds in LOQ concentrations.
Precision

The precision of the method (within–day variations of replicate determinations) was checked by injecting reference compounds nine times at the LOQ levels. The area values were recorded and RSD% was calculated.

Recovery

Spike recovery was carried out by the standard addition method. For the determination of the recovery from the methanol extract, three different concentrations of reference compounds were added prior to the extraction. In each additional level, six determinations were carried out and the mean value of recovery percentage was calculated.

RESULTS

Total phenolic content

The extract yields of aerial parts and roots of *T. sipyleus* were determined as 7.62 and 4.17 % (w/w), respectively. The phenol content of aerial parts and roots were 215.1 ± 2.24 and 152.25 ± 2.31 mg GAE/g extract, respectively.

DPPH (1,1-diphenyl-2-picrylhydrazyl) radical scavenging activity

The extract obtained from the aerial parts of *T. sipyleus* was able to reduce the stable free radical DPPH to the yellow-colored diphenylpicrylhydrazine with an IC₅₀ of 0.703 ± 0.027 mg/mL, showing better activity than the root extract (1.325 ± 0.035 mg/mL). A high amount of the total phenolic content determined in the aerial parts of the plant resulted in a better radical scavenging activity compared to the root. Both the aerial part and the root extracts of *T. sipyleus* exhibited lower antioxidant potential, with higher IC₅₀ values than Trolox (0.043 ± 0.0001 mg/mL) and caffeic acid (0.052 ± 0.0001 mg/mL).

ABTS [2,2'-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)] assay

The ABTS assay results were found to be in parallel with the DPPH radical scavenging activity results. Similarly, the methanol extract obtained from the aerial parts exhibited stronger activity (IC₅₀: 0.869 ± 0.066 mg/mL) than the root extract (IC₅₀: 1.504 ± 0.06 mg/mL) with regard to the higher amount of total phenolics. Both the aerial part and the root extracts of *T. sipyleus* exhibited lower antioxidant potential with higher IC₅₀ values than Trolox (0.042 ± 0.0001 mg/mL).

Identification and quantification of phenolic compounds by HPLC-DAD

As can be seen from the chromatograms obtained from both extracts, the major compound of *T. sipyleus* is rosmarinic acid (Figure 1, 2).

![HPLC chromatogram of T. sipyleus aerial part. 1, chlorogenic acid; 2, caffeic acid; 3, rosmarinic acid; 4, apigenin](image-url)
In approximately 40 min, chlorogenic acid, caffeic acid, rosmarinic acid and apigenin were detected and quantified after evaluating the retention times and UV spectra of the phenolic compounds. For instance, the UV spectra of authentic rosmarinic acid, rosmarinic acid in the aerial parts and rosmarinic acid in the roots were overlaid and all the spectra fit wonderfully. The method was validated and fine results were obtained. The precision of the method was checked by injecting chlorogenic acid, caffeic acid, rosmarinic acid and apigenin nine times at the LOQ levels and was expressed as RSD%: 1.7809, 1.9409, 1.9487 and 1.8126, respectively. Retention times, linear relationships between peak areas and concentrations, test ranges, LOD and LOQ values are given in Table 1. No other effect was determined as it was ensured by the recovery values given in Table 2. The contents of phenolic compounds in different parts of T. sipyleus are given in Table 3. Rosmarinic acid, the major compound, was determined in the aerial parts as 0.8887 ± 0.0016 g/100g dw and in the roots as 0.3454 ± 0.0006 g/100g dw. The occurrence of more antioxidant activity of the aerial parts could be explained to have resulted from the higher rosmarinic acid content.

DISCUSSION

It is obvious that the antioxidant capacity of the T. sipyleus extracts is associated with the presence of phenolic compounds, especially the rosmarinic acid. Rosmarinic acid is an ester of 3,4-dihydroxyphenyllactic acid and caffeic acid. Boraginaceae and the sub-family Nepetoideae of the Lamiaceae, generally contain this highly antioxidant compound which renders a number of interesting biological functions, e.g. antiviral, antibacterial, anti-inflammatory and antioxidant. The presence of rosmarinic acid in medicinal plants, herbs and spices have beneficial and health promoting effects.

Rosmarinic acid and rosmarinic acid hydrolyzed phenolics are very important, maintaining the stability and protection of tissue membranes and proteins from free radical damage. Herb extracts containing rosmarinic acid have widely been used for functional food and pharmacological procedures [21,22]. For this reason qualitative and quantitative analysis of such compounds are getting more important. In the present study, a simple, low-cost and sensitive RP-HPLC method was developed and validated to quantify...

rosmarinic acid as well as caffeic acid, chlorogenic acid, and apigenin in T. sipyleus aerial parts and roots. During the method development, mobile phase components and ratios, flow rate, column temperature and column type were changed to find out the optimum state for the best separation. To present the gradient system, different combinations of water (A), methanol (B) and acetonitrile (C) each containing 0.1 % TFA were attempted. The gradient system in the ratio of A:B:C, 80:12:8 at 0 min, 75:15:10 at 8 min, 70:18:12 at 16 min, 65:20:15 at 24 min, 50:35:15 at 32 min, 25:60:15 at 40 min and 80:12:8 at 45 min, achieved the best separation and was chosen as the gradient solvent system. ACE C18 column (5 μ, 250 mm × 4.6 mm) which is an efficient preference for separation of polar compounds, was used. To eliminate the deviation with regards to temperature differentiation, column temperature was controlled and set to 30 °C. The flow rate was arranged to 0.8 mL/min after trials of different flows.

CONCLUSION

This work reports the development of a simple, low-cost and sensitive RP-HPLC method for the determination of phenolics of T. sipyleus together with the antioxidant activity and total phenolic content. This newly developed and validated RP-HPLC-DAD method will help researchers to determine the phenolic compounds of other natural sources. Furthermore, the significant rosmarinic acid and total phenolics content of T. sipyleus is probably responsible for the high radical scavenging activities of T. sipyleus, thus making the plant a potentially good source of antioxidants for the food, pharmaceutical and cosmetic industries.

ACKNOWLEDGEMENT

The author wishes to thank Prof Dr Zeki AYTAÇ for the identification of the plant used in this work.
