Abstract

Background: There is a number of alternative and complementary therapeutics that are unproven or have not been properly tested. For past twenty years, the transfer of bio-energetic information has been recognized as a novel scientific approach capable of contributing to improved therapy in the management of several diseases through the so-called bio-resonance therapy (BRT). Although BRT was discovered in the late 1980s, it is still poorly studied. The aim of this study was to evaluate the antibacterial effect of water samples transferred with electronic information of vancomycin, a well known drug against methicillin-resistant Staphylococcus aureus (MRSA), by using a BRT device on bacterial cultures.

Material and Methods: MRSA cultures were treated with vancomycin electro-transferred water samples, vancomycin (4.0 and 8.0 µg/mL), sham electro-transferred (water to water) and non-transferred water samples (medium alone). Growth inhibition was evaluated in liquid and solid culture medium, spectrophotometrically and by CFU determination respectively.

Results: The obtained data showed that by transferring vancomycin (4.0 and 8.0 µg/mL) information to water samples, the growth of cultured MRSA was significantly (p<0.05) inhibited (up to 35%), compared with those cultures treated with electro-transferred water to water or cultured in medium alone (0% growth inhibition).

Conclusion: This in vitro study suggests that water samples that are electronically transferred with vibration sustained information of vancomycin are capable of inhibiting growth of axenically cultured methicillin resistant S. aureus.

Key words: Antimicrobial effect, electro-transferred water, bio-resonance, vancomycin, Staphylococcus aureus.

Introduction

Since the 1980s, a promising procedure known as biophysical-information therapy or bio-resonance therapy (BRT) has emerged as an alternative therapeutic method (Fedorowski et al. 2004), but has not yet been properly evaluated. There is an on-going trend toward the use of alternative and complementary therapies, mainly in controlling microbial illnesses. Considering this trend and inability of reaching a consensus on the efficacy of these therapies, the need arises to examine if there is a significant and measurable biological effect of such unorthodox medical procedures.

There is a number of products known as capable of inhibiting microbial growth, including the conventional (orthodox medicine) antibiotics or antimicrobial agents (Mc Donnell and Russell, 1999; Lavin, 2000; Takahashi et al., 2003) or by using unconventional approaches such as electric and magnetic fields; for instance, an early contribution from Rowley et al. (1974), showed an inhibition of infecting microorganisms in human wounds by exposure to alternated electric fields. More recently, Qin et al. (1996) reported that processing liquid foods with high-intensity pulsed electric fields, and inactivated micro-organisms. Conversely, it is known that magnetic fields affect the growth and reproduction of microorganisms and may be used as an antimicrobial procedure (Pothakamury et al., 1993).

Regardless of microbial growth inhibition using unconventional procedures, we have previously observed Entamoeba invadens trophozoite growth and encystation inhibition, using 60 Hz sinusoidal magnetic fields (Rodríguez-De la Fuente et al., 2008). On the other hand, we recently demonstrated that by transferring metronidazole (a well known cytotoxic drug against parasites) information to water samples via an electronic amplifier (BRT device), the growth of axenically-cultured trophozoites of Entamoeba histolytica and Trichomonas vaginalis was significantly inhibited, compared with those cultures treated with sham electro-transferred water samples (Heredia-Rojas et al., 2011). Furthermore, we observed that by transferring amphotericin B information to water samples by a BRT apparatus, the growth of cultured Candida albicans was significantly inhibited (Heredia-Rojas et al., 2012). These results suggest that it is possible to transfer and store biological information to pure water, and that water sample that has undergone such an information transfer, can effectively interact with other biological systems, such as amoeba and yeasts.

Recently, some researchers reported experimental evidence of the developing concept of Electro Magnetic Information Transfer (EMIT) of specific molecular signals directly and continuously on target cell picking up the molecular signals from the source chemical effector (Thomas et al., 2000; Jerman et al., 2005; Foletti et al., 2012).These observations support the hypotheses that water could record and replay the EMIT from biologic active chemical molecules to biological targets.

Contrary to mid-20th century expectations, bacterial infectious diseases have proven increasingly resistant to conventional therapy. Many hospitals encounter nosocomial infections of Staphylococcus aureus, especially in its more recent, methicillin-resistant S. aureus (Chambers and Deleo, 2009; Fry and Baric, 2011; Velázquez-Meza et al., 2013).
In view of this interesting issue involving unorthodox antimicrobial strategies and the possibility to transfer drug information to water molecules by means of resonant circuits, we have undertaken in the present study to further evaluate the antibiotic effect of water samples transferred with electronic information of vancomycin, a well known drug against methicillin resistant *S. aureus*, by using a BRT device.

**Materials and methods**

**Reagents, culture media, and microbial strain**

Vancomycin was obtained from Aventis Pharmaceuticals Inc. (Sommeret, NJ, USA). Methicillin-resistant *Staphylococcus aureus* (MRSA) is a clinical isolate provided by Instituto Mexicano del Seguro Social (I.M.S.S.). The strain was identified by the use of biochemical profiles according to the recommendations of the Manual of Clinical Microbiology (Murray et al., 1999). Bacteria were maintained in nutrient agar (BD Bioxon, Becton Dickinson de México) tubes at 4°C. Before testing, nutrient agar tubes were placed at room temperature for 2 hr, and then a bacteria inoculum was transferred to a nutrient broth (BD Bioxon) tube and aerobically incubated at 35°C for 24 hr. From this, a nutrient agar plate was inoculated and incubated at 35°C for 24 hr, and colonies were isolated and suspended in 0.85% NaCl solution. The bacteria suspension was prepared by adjusting its turbidity to match the 0.5 McFarland standard in 0.85% NaCl solution. To determine cefoxitin strain resistant, the disc diffusion method was used. In brief, 9-cm diameter Petri dishes were prepared with 10 ml of Müeller–Hinton agar medium (BD Bioxon) and inoculated with an embedded Q-tip of the 0.5 McFarland suspension, described above, plated on the agar surface. After drying in a sterile hood, 6-mm diameter disks soaked with 15 µl of cefoxitin were used as controls. The dishes were incubated at 35°C for 24 hr.

Bacterial growth inhibition was determined as the diameter of the inhibition zones around the discs. The growth inhibition diameter was an average of four measurements, taken at four different directions. Tests were performed in triplicate.

**Transmission apparatus**

The equipment used for electronic transmission comprised a bio-resonance therapy oscillator device, Bicom version 4.4 by Regumed (Regulative Medizine Technik GmbH, Germany) serial number 202057299.

**Vancomycin transmission to water**

The source flask containing 4.0 and 8.0 µg/mL of vancomycin respectively, in a total volume of 25.0 ml of bi-distilled water were placed (separately) inside the input coil coupled to a bio-resonance amplifier, whereas in the output coil, a flask containing 25.0 ml of pure bi-distilled and sterile water was placed at room temperature. Vancomycin solutions and bi-distilled water were sterilized by filtration. The oscillator was then turned on for the 15 min transmission period; during this procedure, parameters such as power, voltage, capacitance and impedance remained constant. Thus, the nature of the source flask (vancomycin versus vehicle) was the only variable. According to the bio-resonance device manufacturer, a specific program labelled as #196 was used for electronic transmission substance to substance. At the end of the transmission period, the flasks were kept away from light and stored at room temperature for 1 h before being used in bioassays. For bioassays, 500µL of transferred-water or sham-treated water were added to each culture tube.

**Experimental Design**

The experiments using axenically cultured MRSA included the following treatment regimens and controls: (a) cells treated with electronically-transferred 4.0 µg/mL, and (b) 8.0 µg/mL vancomycin water samples, as explained above, (c) cells treated with sham electro-transferred water samples, this is transferring the information from pure water to water, used as the control for a possible artefact effect induced by the bio-resonance device on water samples, (d) cells treated with non-transferred water, or medium alone, as a negative control, (e) cells treated with 4.0µg/mL of vancomycin as a positive control and, (f) cells treated with 8.0µg/mL of vancomycin as a positive control. Three cultures were included for each treatment regimen and controls. In all experiments in which transmitted vancomycin was compared with transmitted vehicle, the source flasks were randomized and blinded before each experiment. Therefore, the observed effect cannot be attributed to uncontrolled systematic factors (operator bias, temperature, time…) but to the independent variable, the content of the source flask.

**Antimicrobial activity of electronically-transmitted vancomycin to water**

We selected methicillin resistant *S. aureus* since it is a bacterium that is resistant to many antibiotics and is associated with nosocomial infection, particularly nosocomial pneumonia, surgical wound infection, and bloodstream infection. The percentage of microbial growth inhibition by electronically-transmitted vancomycin to water in liquid medium by spectrophotometry was determined as follows: One milliliter of MRSA suspensions (106 CFU/ml) was added to 4-ml (10 X 75 mm) round-bottom screw cap borosilicate culture tubes (VWR International S. de RL de C.V., Tultitlán, Estado de México) containing 0.5 ml Müeller–Hinton nutrient broth (BD Bioxon) (5 X 105 CFU/ml, final bacteria concentration). After this, 0.5 ml vancomycin at 4 µg/ml and 8 µg/ml were independently added to 3 of these culture tubes; 0.5 ml electronically-transmitted vancomycin to water at 4 µg/ml and 8 µg/ml were independently added to other three of the culture tubes, and bacterial suspensions treated with sham electro-transferred water samples and non-transferred water, considered as medium alone (negative control), to a final volume of 2 ml for all culture tubes. Treatment and control culture tubes in triplicates were then incubated for 24 hr at 35°C, after which optical densities at 625nm were read in a Turner SP-830 spectrophotometer (Barnstead, Dubuque, IA, USA). For CFU determination, 100 µl of 1:10-8 dilutions of the treatment and control culture tube microbial suspensions used in the preceding experiment, were plated in nutrient agar (BD Bioxon) by surface spreading using a sterile glass rod. Plates were then incubated at 35°C for 24 hr and colonies were counted in a colony counter (ULB-100, Lighbox 37864-2000, Scienceware BEL-ART products, Pequannock, NJ, USA).

**Statistical Analysis**

The statistical differences were calculated among groups for bacterial growth by using analysis of variance for normal distributions and the correspondent Tukey test for establishing individual differences. The normality of the data was estimated by means of Kolmogorov-Smirnov test (*p*<0.05). All analyses were done using the SPSS package version 20.0. Differences were considered to be significant when the probability values were lower than 0.05.
The present study evaluated the effect of electronically transmitted vancomycin to water samples on *in vitro* MRSA growth. It was observed a similar pattern of MRSA growth inhibition on liquid and solid culture media; electro-transferred vancomycin at either 4 µg/ml or 8 µg/ml, and vancomycin alone caused significant (*p*<0.05) up to 35% and/or up to 99% bacterial growth inhibition, respectively, compared with electrotransferred water to water and medium alone controls. The antimicrobial effect of electro-transferred vancomycin was not concentration-dependent (Figs. 1 and 2).

**Figure 1:** Effects of electro-transferred water on MRSA growth inhibition on liquid culture medium. MRSA growth after exposure to electronically-transmitted vancomycin to water in liquid culture medium was determined spectrophotometrically, as explained in the text. Controls used included vancomycin (4.0 µg/mL and 8.0 µg/mL) as a positive (antibacterial) control, and electro-transferred water to water (used as the control for a possible artefact effect induced by the bio-resonance device on water samples) and medium alone bacterial growth controls. Bars represent arithmetical grouped means ± SEM.

**Figure 2:** Effect of vancomycin electro-transferred water samples on MRSA growth inhibition on solid culture medium. MRSA growth after exposure to electronically-transmitted vancomycin to water in solid culture medium was determined by CFU determination, as explained in the text. Controls used included vancomycin (4.0 µg/mL and 8.0 µg/mL) as a positive (antibacterial) control, and electro-transferred water to water and medium alone bacterial growth controls. Bars represent arithmetical grouped means ± SEM.

**Discussion**

The effect of vancomycin electro-transferred water samples on MRSA growth was evaluated. A statistically significant reduction of *S. aureus* growth was observed after pure cultures were treated with water samples electro-transferred in a BRT device by using a specific program called “substance to substance transference”.
bio-resonance procedures, rather we showed evidence for a significant and measurable biological effect induced by electro-transferred water samples that acquire, or at least mimics, the chemical information transferring properties against E. histolytica and S. aureus (1995) demonstrated that the metamorphosis of By the way, Teixeira (2007) proposed that the presence of other molecules (solute ions) and dissolved gases in the water can be produced in aqueous dilutions of the human immunodeficiency virus DNA. This also opens the way to the development of highly sensitive detection system for some microbial illnesses in humans and animals. The basis for an understanding of the antimicrobial effects of bio-resonance techniques is the assumption that the alternating electromagnetic fields, which are detectably emitted by living organisms and molecules and are characterized by intensity and frequency, contain biologically significant information that is used for transmitting a number of signals between cells, tissues, and even molecules (Likhoded et al., 2007). Recently, a novel property of DNA showing the capacity of some microbial DNA sequences to induce electromagnetic waves at high aqueous dilutions was reported (Montagnier et al., 2009a; Montagnier et al., 2009b). They found that electromagnetic signals of low frequency can be produced in aqueous dilutions of the human immunodeficiency virus DNA. This also opens the way to the development of highly sensitive detection system for some microbial illnesses in humans and animals.

To our knowledge, in the existing literature there are no original articles published on MRSA growth inhibition by transferring antibiotic drugs to water samples. On the other hand, as bio-resonance procedures are challenged by some, research trials conducted primarily in Russia, Germany, and Eastern Europe, indicated that electromagnetic waves can affect biology in single-cell models that can include microorganisms (Islamov et al., 2002). Recently, a bacteriostatic effect was observed when cultures of Staphylococcus aureus Wood-46 were treated with the help of Molecular Resonance Effect Technology (MRET) a US-patented technology to activate water by means of electromagnetic waves (Vysotskii et al., 2009a). It was demonstrated that under definite conditions, activated MRET water possesses very strong bactericidal action of electromagnetic waves, because electro-transferred water samples are under electromagnetic influence of the BRT apparatus. Since 1996, it is known that water clusters are extremely sensitive to the influence of physical factors such as electromagnetic fields, and even low and ultra-low fields (Liu et al., 1996). It has been proposed that this water capacity to acquire paradoxical configurations induced by low and extremely low intensity electromagnetic fields should be considered when trying to explain resonant intermolecular transfer of electromagnetic energy in liquid water samples (Woutersen and Bakker, 1999). Recently, it has been reported that electromagnetic transmission of chemical information can be stored in the electric dipole moments of water in close analogy to the manner in which magnetic moments store information on a computer disk (Thomas et al., 2000). Furthermore, Del Giudice et al. (2003) for the present study, one working hypothesis was that molecules can communicate with each other, exchanging information without being in physical contact and that at least some biological functions can be mimicked by certain energetic modes characteristics of a given molecule (Thomas, 2007). In addition, our results agreed with the hypothesis that aqueous system could be able to record, store, and transfer biophysical active information to biological targets (Smith, 2004; Foletti et al., 2013).

There is a big challenge in this 21st century; serious infections caused by micro-organisms that have become resistant to commonly used antibiotics have become a major global healthcare problem. For instance, a question has been raised: are we in the post-antibiotic era? (Alanis, 2005). Independently of the answer, it is necessary to explore other antimicrobial strategies as the one shown in the present study. We consider that today’s biology (Wounded by the molecular approaches developed since about 1940, is suffocated by an immense number of experimental data on molecular aspects of biological functions, which present an extremely fragmented view on the living state. Thus, the holistic approach to biological studies is a complement to the contemporary practice. Field theories, as a central element of holistic models, possibly will be dominant models in the future. In addition, we believe that it is important to draw the scientific community’s attention to experimental results obtained by an unorthodox approach. Every really new approach is labelled as unconventional until we fully disclose its mechanism of action. As a matter of fact, in the biological domain we are more acquainted with chemical than with physical approaches, but the last ones, in a near future, may become the next step in the evolution of therapeutic methods.

In conclusion, our in vitro study suggests that water samples that are electronically transferred with vibration sustained information of vancomycin are capable of inhibiting growth of axenically cultured methicillin resistant S. aureus. However, with the results shown here, we are neither supporting any therapeutic technique nor recommending bio-resonance procedures, rather we showed evidence for a significant and measurable biological effect induced by electro-transferred water samples that acquire, or at least mimics, the chemical information transferring procedure, given the properties of vancomycin. Furthermore, an advantage of using a single-cell model for evaluating the effectiveness of bio-resonance technique is that the placebo effect, claimed by those who refuse any alternative or complementary therapeutics, is absent.
Acknowledgements

We are grateful to Dr. Antonio Cayetano Torres-Flores for his technical assistance in transferring water samples. We also thank Dra. Michaela Beltscheva of the Bulgarian Academy of Sciences, for critically revising the manuscript. The present study was partially funded by PAICYT grant CN981-11 to J. Antonio Heredia-Rojas.
